Not that this is a big problem as usually, the Java version of a compiled application can only be executed by administrators (or root) when their path variable is set. The Java launcher utility runs the package Explorer context menu and provides the user with the choice of executing a Java application, searching in a JAR file or exploring the files within a JAR archive. The Java launcher is very easy to use. A warning dialog is presented that requests the user to choose between 'Open' and 'Run'. A file, JAR or Java application will be opened as per the user's decision. In the present implementation of the Java launcher, the selectable file types are directories, executable files and JAR archives. The Java Launcher has a rather simple interface. The left window is used for the opening of the file types that are available. Selecting a JAR archive opens the archive and all the contained files. A double-click on a file name opens the associated file in a separate window. Double-clicking on a JAR archive will open the JAR file in Explorer. Comparing nLite to the other freeware in this list, nLite offers a more complete package than any of them. It has options that make it easier to use, as well as more advanced features, such as the ability to compress files, convert video, create DVD/Blu-ray discs and lots more. It can also be used to remove your PC's Windows operating system and replace it with its own - meaning that you can run the full version of Windows and then only use nLite as you need to. The most important consideration when choosing which freeware to use is how much time you have available, and how much money you have to spend. If you are happy with the level of support that the programs offer, and you're not overly concerned with the security and stability of your operating system, then nLite is probably the one to go for. I have got list of urls and print one line at a time, but I want to print whole list, if any in requests.get is None. urls = ["", "", ""] for url in urls: requests.get(url) print(url) Output: /2 None I want to print all the urls if none is returned A: One solution is to iterate over urls and if the request returns None, append the url to the list. import requests urls = ["", "", ""] print [x for x in urls if x] [Another solution is to check if the request is None first and then not raise an error. import requests urls = ["", "", ""]
