# {Diablo 3 Crack [2021] Password Txt}

Graham told us that dictionaries should be narrowed in the following manner: The dictionary words with the highest potentials(essentially, the most frequently used ones) should be first. Each word should only be added to a dictionary once it has been found at least twice in the same document(that is, a separate document from that of the username that is being cracked). Words that are also found within the document should be given preference over words that appear in a different document. Now that we had a better foundation for his attack, it was time to put it to work. The trouble is that, as he said, it was too broad. The term "life" will be found in 1000 documents, but only once. In Diablo II: Resurrected, it will be found for each account 10,000 times. For a security professional, that's a problem. It means that we won't find the term in the 1,000 documents associated with an account at all. That's not good. The solution is to ignore the term entirely and simply try to brute force the password until we find a match. That's exactly what Graham did. How long would a brute force take? It turns out that once you have a dictionary with 400,000 words, the average time to find a password on a single disk will come down to about 4 hours; on a modern laptop, that's the same time it would take to crack a 4 character password, which is a feat that we can all certainly relate to. To account for the fact that some of the usernames will have more than two characters in the password, we can increase this number. Using a dictionary of 1,000,000 words, we can average a success rate of 1 in 650 per document. For each 8 character password, it will take 2,500 documents to find a match, so on average it will take 3.6 hours. On a laptop, this adds up to around 120 minutes or 3.3 hours.

**Download**

Once we've found enough matches, we can then move on to brute-forcing, which is cracking long and complex passwords. With that in mind, we can increase the time spent cracking passwords and have it happen every three hours rather than every 12 hours.

This will ensure that our bruteforce script won't crash and burn on a single day if it happens to run into a single document that has a password

---

in it. With that in place, and with this additional step, we now have the ability to not only find passwords, but to make it as easy as possible for the user to guess. I need to stress the importance of beginning password attacks with the goal of finding a match, not only to prevent future password attacks, but to make the finding as convenient as possible to the user in case they do have a password to fix. Instead of trying to hash an entire wordlist, Hashcat lets you pick a specific word, such

---

as the first word in my password list, hash it, and try to crack the rest of the words in the list with that perfecthash. Though the list is long and I was interested in cracking only the first characters of each word, Hashcat lets you choose the smallest possible perfecthash or just pick the best hash using every cryptographically generated Unicode character. I did not want to waste a perfectly good computer on the three wordlist files I had just cracked. Moreover, because I

---

knew my dictionary of words  
that might hash to the  
perfecthash was only a small  
collection of ~200 words (and  
this was only the first letter of  
each word, not the full words  
like you might find in a  
cracker's dictionary), I was  
surprised that it went past  
wordlist 5ec8ef588b
